In situ hybridization has become a standard method for localizing DNA or RNA sequences in cytological preparations. We developed two methods to extend this technique to the transmission electron microscope level using mouse satellite DNA hybridization to whole mount metaphase chromosomes as the test system.

Electron microscopy in situ hybridization (EM-ISH) represents a powerful method that enables the localization of specific sequences of nucleic acids at high resolution. We provide here an overview of three different nonisotopic EM-ISH approaches that allow the visualization of nucleic acid sequences in cells.

In situ hybridization is a type of hybridization that uses a labeled complementary DNA, RNA or modified nucleic acids strand to localize a specific DNA or RNA sequence in a portion or section of tissue or if the tissue is small enough, in the entire tissue, in cells, and in circulating tumor cells. This is distinct from immunohistochemistry, which usually localizes proteins in tissue sections. In situ hybridization is used to reveal the location of specific nucleic acid sequences on chromosomes

In situ hybridization - Wikipedia

In situ hybridization (ISH) is a powerful and sensitive method to localize target messenger ribonucleic acids (mRNAs) of specific genes in tissue sections. Initially ISH methods used radioactively labeled sense RNA probes (riboprobes). More recently, comparably sensitive nonradioactive methods have been developed and adapted by many laboratories.

In situ hybridization demonstrated growth hormone mRNA expression in adenoma cells. Clinically silent somatotroph adenomas represent a hitherto undescribed entity; electron microscopy shows that they consist of somatotrophs, and express growth hormone mRNA but do not secrete growth hormone in amounts needed to raise substantially serum growth hormone levels and cause acromegaly.

The introduction in the late 1960s of in situ hybridization (ISH) techniques (Buongiorno-Nardelli and Amaldi 1970; Gall and Pardue 1969; John et al. 1969) opened a new era in histology and cell biology. Whereas immunocytochemical methods can demonstrate only the presence of synthesized protein molecules, irrespective of any routing in the tissue, the recognition in a tissue and in a cell of ...

In fluorescent "in situ" hybridization refers to the cellular placement of the probe Probe size is important because longer probes hybridize less specifically than shorter probes, so that short strands of DNA or RNA (often 10–25 nucleotides) which are complementary to a given target sequence are often used to locate a target.

Fluorescence in situ hybridization - Wikipedia

With paraformaldehyde-fixed sections, the nonradioactive in situ hybridization method provides detection of individual, very small glial progenitor cells in embryonic development. Small, isolated cells expressing oligodendrocyte specific messages can be detected in the neuroepithelium at embryonic and postnatal stages.

Electron microscopy permits the detailed study of cell relationships within tissues and organelles within cells. Two ultrastructural techniques in which gold probes have proven invaluable are immunocytochemistry and in situ hybridization, and these will be described here.

Additionally, we have performed in situ hybridization for SARS-CoV-2 RNA in eight biopsies from patients with active COVID-19 who had evidence of kidney disease and were unable to detect virus RNA in renal tissue, despite adequate positive controls. This appears to be in contrast with a recent study that showed SARS-CoV-2 RNA could be detected by RT-PCR within renal tissue in 13 of 22 ...
